

# Object-Oriented Design I

- Objectives - when we have completed this set of notes, you should be familiar with:
  - Software development activities
  - How classes and objects needed for a program may be determined
  - Relationships that can exist between two classes
  - The static modifier

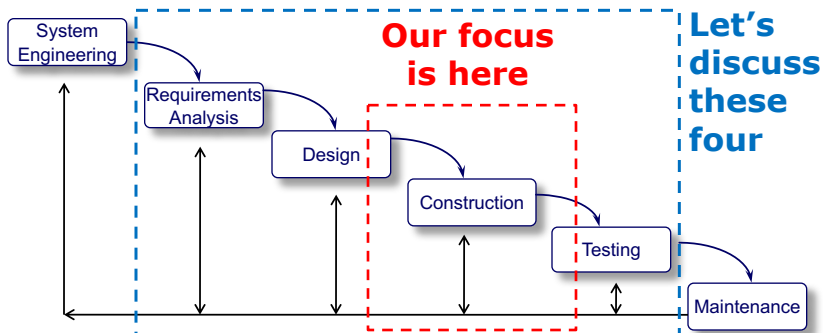

# Program Development

- The creation of software may include the following activities:
  - Establishing **system** hardware/software requirements, boundaries, interfaces, etc. (esp. for embedded systems)
  - Establishing/analyzing the software **requirements**
  - creating a software **design**
  - **Constructing** the **code (a.k.a. Implementation)**
  - **testing** the implementation
  - **Maintaining** the software after delivery

## Program Development

- The activities below can be linear, can overlap/interact, or can be naturally cyclical

- Many variants of the process model

## Requirements

- *Software requirements* specify the tasks that a program must accomplish
  - what to do (not how to do it)
- Translating what the customer wants into what the software should accomplish.
- Sample customer requirement: "I need software that will provide interoperability between disparate C4ISR systems." (concept of Command, Control, Communications, Computers, Intelligence, Surveillance and Reconnaissance)
  - It's not time to start coding yet.

# Requirements

- A simple requirement: "I want something to check products against their barcodes."
- A partial requirements document:

**The user must be allowed to specify each product by its primary characteristics, including its name and product number. If the bar code does not match the product, then an error should be generated to the message window and entered into the error log. The summary report of all transactions must be structured as specified in section 7.A.**

# Design

- *Software design*: how a program will accomplish its requirements.
- An object-oriented design:
  - Classes, methods, and data needed
  - Relationships between/among classes
  - How information will be stored (databases)
  - Etc.
- Your project descriptions contain both requirements and design elements.

# Object-Oriented Design and Programming

- Objects and attributes (fields) are generally nouns, and methods are generally verbs

The **user** must be allowed to specify each **product** by its primary **characteristics**, including its **name** and **product number**. If the **bar code** does not match the **product**, then an **error** should be generated to the **message window** and entered into the **error log**. The **summary report** of all **transactions** must be structured as specified in section 7.A.

## Identifying Classes (Objects) and Attributes

- Generally, classes that represent objects should be given names that are singular nouns (e.g., Triangle); methods are should be given names that are verbs, verb phases, or a noun with an implied verb (e.g., a perimeter() method in Triangle has the implied verb calculate).
  - Class: Product
    - Attributes: name, product number, barcode
    - Methods: checkBarcode(), generateErrorMessage(), createSummaryReport()
- We are free to instantiate as many Product objects as needed

## Identifying Classes (Objects) and Attributes

- When a class becomes too complex, it often should be decomposed into multiple smaller classes to distribute the responsibilities

- **Class: Product**

- Attributes: name, product number, barcode

- **Class: Product**

- Attributes: name, product number, barcode

- **Class: Barcode**

- Attributes: version, format, data, visual representation, etc

Might be complex enough to warrant a separate class

## Construction

- *Construction*: turning design into source code
- Novice programmers often think that writing code is the hard part of software development; actually it may be the most straightforward step
  - The important/hard decisions were made during requirements and design stages
- Construction (a.k.a. Implementation) focuses on coding (and many times fine-grained design) as well as coding style (e.g., Checkstyle) and documentation (Javadoc comments); usually includes unit testing (informal or formal)

# Testing

- *Testing* attempts to ensure that the program will solve the intended problem
  - A program should be thoroughly tested with the goal of finding errors/defects
- *Testing* discovers errors or defects; *debugging* locates and corrects/removes them
- We'll discuss the details of the testing process later
- We'll use the JUnit Framework for unit testing
  - Your programs are graded by running the usual reference tests as well as by how well your own testing was carried out

*Now back to the details of Java . . .*

## Static Class Members

- Static methods are invoked using the class name  
  
Example: `result = Math.sqrt(25)`
- Suppose Person class has a name field and you have a static method called `getName()`; what name would `Person.getName()` retrieve?
- **A static method cannot access the instance variables of its class.**
  - This is because static methods can be invoked before an object of the class is instantiated

## Static Methods

```
public class Helper
{
    public static int cube (int num)
    {
        return num * num * num;
    }
}
```

Because it is declared as **static**, the method can be invoked as

```
value = Helper.cube(5);
```

## Static Variables

- If a variable is declared as static, it exists at the class level rather than for each instance

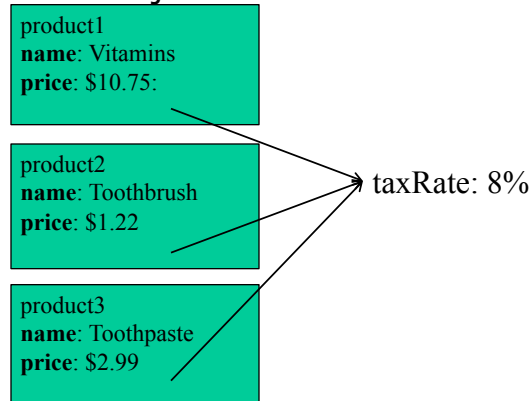

```
private static double taxRate;
```

- Space is reserved in memory when the class is first referenced
- A static variable is the same for all instances of the class (i.e., it is shared among the instances) and it is accessible from all instance methods in the class
- If the value of a variable needs to be unique for each object, then it should **not** be static.

## Static Variables

- In this case, the taxRate is the same for all objects; changing the static variable changes it for all objects of the class

## The *static* Modifier

- Static methods are called *class methods* and static variables are called *class variables*
- Instance methods can reference instance variables and static variables
- Static methods can only access static variables of the class, not instance variables
- Before you declare a field to be a static variable, consider the following:
  - Should the value of the variable be the same for all objects? That is, should it be shared by all objects?
  - If the value of the variable is changed, should it change for all objects?

**Q1**

## Static Class Members

- Static methods and static variables often work together
- The following example keeps track of how many **Magazine** objects have been created using a static variable, and makes that information available using a static method
- See [Magazine.java](#) and [MagazineExample.java](#)
- See [StaticExample.java](#)

## Class Relationships

- A class may depend on one or more other classes in a program. The dependency relationship between two classes can be described as:
  - General Dependency: A *uses* B
  - Aggregation: A *has-a* B
  - Inheritance: A *is-a* B (details later in the course)
- General dependency: The ProductList class uses the DecimalFormat class for formatting
- Aggregation: The ProductList class **has a** set of items of type Product (aggregation)

## Dependency

- General dependency: one class relies on another in some way (e.g., creating an instance; by invoking its methods)
- We don't want a lot of classes with complex dependencies, but we also don't want very large, complex classes either
- Some dependencies occur between objects of the same class. Example, the `concat` method of the `String` class takes a `String` parameter

```
str3 = str1.concat(str2);
```

## Aggregation

- An *aggregate* is an object that is made up of one or more other objects
- Therefore aggregation is a *has-a* relationship
  - A car *has a* chassis
  - A product *has a* barcode
- An aggregate object has one or more instance variables (instance fields) that are references to objects of other classes

[Q2](#) [Q3](#)

## Aggregation Dependencies in UML

- [Magazine2\\_project.gpj](#) – open the project in jGRASP, compile, then generate UML class diagram. What type of relationships exist between Magazine2Example and Magazine2? Between Magazine2 and Publisher?
- In jGRASP, general dependency and the aggregation relationships are both shown as red, dashed arrows.

## The this reference

- The `this` reference allows an object to refer to itself in constructors/methods inside its class
- For example, the constructor of the `Magazine2` class could be written as follows:

```
public Magazine2(String title, int pages,
                 String thePublisher, String theCity)
{
    this.title = title;
    this.pages = pages;
    publisher = new Publisher(thePublisher, theCity);
    count++;
}
```

Our coding standard (i.e., our Checkstyle rules) requires unique names for parameters, so using the `this` reference in this way breaks this rule.
